The definition of prices represents an important issue in household demand analysis employing budget survey data. The first problem is that the real prices of purchased goods are not usually available. Instead, the overall quantity and expenditures for a good are often reported. Hence, unit values can be calculated and employed instead of real prices, regional prices, or price indices. The second problem is that for the households that do not report expenditures or do not buy the good at the moment of a survey, we do not have information on their unit values. The literature offers several treatments. Assign to those observations sample mean of the other unit values, input regional or national prices, estimate missing prices on the base of other observations, or delete these observations. We compare these techniques and evaluate them on an empirical example. We analyse the demand for six meat categories of Czech households through an AIDS model for 2012-2016. We choose meat because of three factors. It is the most analysed food item in the history, the consumption of red meat contributes to the problem of population obesity, meat together with dairy products represent 80 % of CO₂ emissions coming from food consumption. Results show that income elasticities are only slightly influenced by the treatment of missing unit values. On the contrary, the estimates of own-price elasticities where the prices play crucial role differ significantly, up to 28 percentage points. Such difference can highly influence the conclusions of studies exploring environmental taxes, calories intake, distributional impacts, and other policy propositions. Although our results are sample specific, we want to bring the discussion about the replacement of missing price information and remind that the chosen method should be very well discussed and verified to be suitable before being employed in the concrete analysis.

Index Terms: Demand, Food, Household, Elasticity, Unit Values, Selectivity
